

Повторим матричное дифференцирование

i Example

Найти гессиан $\nabla^2 f(x)$, если $f(x) = \langle x, Ax \rangle - b^T x + c$.

i Example

Найти гессиан $abla^2 f(x)$, если $f(x) = \langle x, Ax \rangle - b^T x + c$.

1. Распишем дифференциал df

$$\begin{split} df &= d \left(\langle Ax, x \rangle - \langle b, x \rangle + c \right) \\ &= \langle Ax, dx \rangle + \langle x, Adx \rangle - \langle b, dx \rangle \\ &= \langle Ax, dx \rangle + \langle A^Tx, dx \rangle - \langle b, dx \rangle \\ &= \langle (A + A^T)x - b, dx \rangle \end{split}$$

Что означает, что градиент $\nabla f = (A + A^T)x - b$.

i Example

Найти гессиан $abla^2 f(x)$, если $f(x) = \langle x, Ax \rangle - b^T x + c$.

1. Распишем дифференциал df

$$\begin{split} df &= d \left(\langle Ax, x \rangle - \langle b, x \rangle + c \right) \\ &= \langle Ax, dx \rangle + \langle x, Adx \rangle - \langle b, dx \rangle \\ &= \langle Ax, dx \rangle + \langle A^Tx, dx \rangle - \langle b, dx \rangle \\ &= \langle (A + A^T)x - b, dx \rangle \end{split}$$

Что означает, что градиент $\nabla f = (A + A^T)x - b$.

i Example

Найти гессиан $\nabla^2 f(x)$, если $f(x) = \langle x, Ax \rangle - b^T x + c$.

1. Распишем дифференциал df

$$\begin{split} df &= d \left(\left\langle Ax, x \right\rangle - \left\langle b, x \right\rangle + c \right) \\ &= \left\langle Ax, dx \right\rangle + \left\langle x, Adx \right\rangle - \left\langle b, dx \right\rangle \\ &= \left\langle Ax, dx \right\rangle + \left\langle A^Tx, dx \right\rangle - \left\langle b, dx \right\rangle \\ &= \left\langle (A + A^T)x - b, dx \right\rangle \end{split}$$

Что означает, что градиент $\nabla f = (A + A^T)x - b$.

2. Найдем второй дифференциал $d^2f = d(df)$, полагая, что $dx = dx_1 = {\rm const}$:

$$\begin{split} d^2f &= d\left(\langle (A+A^T)x-b, dx_1\rangle\right) \\ &= \langle (A+A^T)dx, dx_1\rangle \\ &= \langle dx, (A+A^T)^Tdx_1\rangle \\ &= \langle (A+A^T)dx_1, dx\rangle \end{split}$$

Таким образом, гессиан: $abla^2 f = (A + A^T)$.

Повторим матричное дифференцирование

i Example

Найти гессиан $abla^2 f(x)$, если $f(x) = \ln \langle x, Ax \rangle$.

i Example

Найти градиент $\nabla f(x)$ и гессиан $\nabla^2 f(x)$, если $f(x) = \ln{(1 + \exp\langle a, x \rangle)}$

i Example

Найти градиент $\nabla f(x)$ и гессиан $\nabla^2 f(x)$, если $f(x) = \ln{(1 + \exp{\langle a, x \rangle})}$

1. Начнем с записи дифференциала
$$df$$
. Имеем:

$$f(x) = \ln\left(1 + \exp\langle a, x \rangle\right)$$

Используя правило дифференцирования сложной функции:

$$df = d\left(\ln\left(1 + \exp\langle a, x\rangle\right)\right) = \frac{d\left(1 + \exp\langle a, x\rangle\right)}{1 + \exp\langle a, x\rangle}$$

теперь посчитаем дифференциал экспоненты:

$$d\left(\exp\langle a, x\rangle\right) = \exp\langle a, x\rangle\langle a, dx\rangle$$

Подставляя в выражение выше, имеем:

$$df = \frac{\exp\langle a, x \rangle \langle a, dx \rangle}{1 + \exp\langle a, x \rangle}$$

i Example

Найти градиент $\nabla f(x)$ и гессиан $\nabla^2 f(x)$, если $f(x) = \ln{(1 + \exp{\langle a, x \rangle})}$

1. Начнем с записи дифференциала
$$df$$
. Имеем:

$$f(x) = \ln\left(1 + \exp\langle a, x \rangle\right)$$

Используя правило дифференцирования сложной функции:

$$df = d\left(\ln\left(1 + \exp\langle a, x\rangle\right)\right) = \frac{d\left(1 + \exp\langle a, x\rangle\right)}{1 + \exp\langle a, x\rangle}$$

теперь посчитаем дифференциал экспоненты:

$$d\left(\exp\langle a, x\rangle\right) = \exp\langle a, x\rangle\langle a, dx\rangle$$

Подставляя в выражение выше, имеем:

$$df = \frac{\exp\langle a, x \rangle \langle a, dx \rangle}{1 + \exp\langle a, x \rangle}$$

i Example

Найти градиент $\nabla f(x)$ и гессиан $\nabla^2 f(x)$, если $f(x) = \ln (1 + \exp(a, x))$

1. Начнем с записи дифференциала
$$df.$$
 Имеем:

$$f(x) = \ln{(1 + \exp\langle a, x \rangle)}$$

Используя правило дифференцирования сложной

функции: $df = d\left(\ln\left(1 + \exp\langle a, x \rangle\right)\right) = \frac{d\left(1 + \exp\langle a, x \rangle\right)}{1 + \exp\langle a, x \rangle}$

теперь посчитаем дифференциал экспоненты:

 $df = \frac{\exp(a, x)\langle a, dx \rangle}{1 + \exp(a, x)}$

$$d\left(\exp\langle a,x\rangle\right)=\exp\langle a,x\rangle\langle a,dx\rangle$$

Подставляя в выражение выше, имеем:

2. Для выражения df в нужной форме, запишем:

$$df = \left\langle \frac{\exp\langle a, x \rangle}{1 + \exp\langle a, x \rangle} a, dx \right\rangle$$

Напомним, что функция сигмоиды определяется

как: $\sigma(t) = \frac{1}{1 + \exp(-t)}$

$$\sigma(t) = rac{1}{1 + \exp(-t)}$$
Таким образом, мы можем переписать

 $df = \langle \sigma(\langle a, x \rangle) a, dx \rangle$

дифференциал:

 $\nabla f(x) = \sigma(\langle a, x \rangle)a$

i Example

Найти градиент $\nabla f(x)$ и гессиан $\nabla^2 f(x)$, если $f(x) = \ln \left(1 + \exp \langle a, x \rangle \right)$

3. Теперь найдем гессиан с помозью второго дифференциала:

$$d(\nabla f(x)) = d\left(\sigma(\langle a, x \rangle)a\right)$$

Так как вектор a константа, нам необходимо продифференцировать лишь сигмоиду:

$$d\left(\sigma(\langle a,x\rangle)\right) = \sigma(\langle a,x\rangle)(1-\sigma(\langle a,x\rangle))\langle a,dx\rangle$$

То есть:

$$d(\nabla f(x)) = \sigma(\langle a, x \rangle)(1 - \sigma(\langle a, x \rangle))\langle a, dx \rangle a$$

Запишем гессиан:

$$\nabla^2 f(x) = \sigma(\langle a, x \rangle)(1 - \sigma(\langle a, x \rangle))aa^T$$

Автоматическое дифференцирование

•••

I think the first 40 years or so of automatic differentiation was largely people not using it because they didn't believe such an algorithm could possibly exist.

Link to a nice visualization &, where one can see, that gradient-free methods handle this problem much slower, especially in higher dimensions.

i Question

Is it somehow connected with PCA?

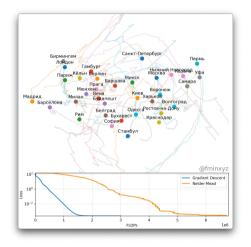

Рис. 3: Ссылка на анимацию

Рассмотрим следующую задачу оптимизации

$$L(w) \to \min_{w \in \mathbb{R}^d}$$

Рассмотрим следующую задачу оптимизации

$$L(w) \to \min_{w \in \mathbb{R}^d}$$

вместе с методом градиентного спуска (GD)

$$w_{k+1} = w_k - \alpha_k \nabla_w L(w_k)$$

Рассмотрим следующую задачу оптимизации

$$L(w) \to \min_{w \in \mathbb{R}^d}$$

вместе с методом градиентного спуска (GD)

$$w_{k+1} = w_k - \alpha_k \nabla_w L(w_k)$$

Можно ли заменить $\nabla_w L(w_k)$, используя, лишь информацию нулевого порядка о функции?

Рассмотрим следующую задачу оптимизации

$$L(w) \to \min_{w \in \mathbb{R}^d}$$

вместе с методом градиентного спуска (GD)

$$w_{k+1} = w_k - \alpha_k \nabla_w L(w_k)$$

Можно ли заменить $\nabla_w L(w_k)$, используя, лишь информацию нулевого порядка о функции? Да, но есть нюанс.

¹I suggest a nice presentation about gradient-free methods

Можно ли заменить $\nabla_w L(w_k)$, используя, лишь информацию нулевого порядка о функции? Да, но есть нюанс.

One can consider 2-point gradient estimator G:

$$G = d\frac{L(w + \varepsilon v) - L(w - \varepsilon v)}{2\varepsilon}v,$$

where v is spherically symmetric.

$$\frac{\partial L}{\partial w_k}(w) \approx \frac{L(w+\varepsilon e_k) - L(w)}{\varepsilon}, \quad e_k = (0,\dots,\frac{1}{k},\dots,0)$$

i Question

If the time needed for one calculation of L(w) is T, what is the time needed for calculating $\nabla_w L$ with this approach?

The naive approach to get approximate values of gradients is **Finite differences** approach. For each coordinate, one can calculate the partial derivative approximation:

$$\frac{\partial L}{\partial w_{h}}(w) \approx \frac{L(w+\varepsilon e_{k}) - L(w)}{\varepsilon}, \quad e_{k} = (0,\dots,\frac{1}{k},\dots,0)$$

i Question

If the time needed for one calculation of L(w) is T, what is the time needed for calculating $\nabla_w L$ with this approach?

Answer 2dT, which is extremely long for the huge scale optimization. Moreover, this exact scheme is unstable, which means that you will have to choose between accuracy and stability.
