

**Examples of Linear Programms** 

### What is Linear Programming?

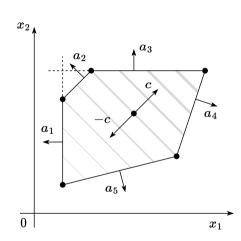

Generally speaking, all problems with linear objective and linear equalities/inequalities constraints could be considered as Linear Programming. However, there are some formulations.

$$\min_{x \in \mathbb{R}^n} c^\top x$$
 s.t.  $Ax \leq b$  (LP.Basic)

for some vectors  $c\in\mathbb{R}^n$ ,  $b\in\mathbb{R}^m$  and matrix  $A\in\mathbb{R}^{m\times n}$ . Where the inequalities are interpreted component-wise.

### What is Linear Programming?

Generally speaking, all problems with linear objective and linear equalities/inequalities constraints could be considered as Linear Programming. However, there are some formulations.

$$\min_{x \in \mathbb{R}^n} c^\top x$$
 (LP.Basic) s.t.  $Ax \leq b$ 

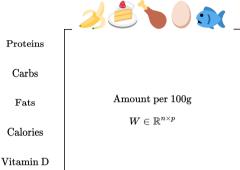

for some vectors  $c\in\mathbb{R}^n$ ,  $b\in\mathbb{R}^m$  and matrix  $A\in\mathbb{R}^{m\times n}$ . Where the inequalities are interpreted component-wise.

**Standard form.** This form seems to be the most intuitive and geometric in terms of visualization. Let us have vectors  $c \in \mathbb{R}^n$ ,  $b \in \mathbb{R}^m$  and matrix  $A \in \mathbb{R}^{m \times n}$ .

$$\min_{x \in \mathbb{R}^n} c^\top x$$

s.t. Ax = b (LP.Standard)  $x_i > 0, i = 1, \dots, n$ 

# **Example: Diet problem**

$$\min_{c \, \in \, \mathbb{R}^p, \, ext{price per 100g}} c^T x$$

$$x \in \mathbb{R}^n, ext{nutrient requirements} \qquad egin{array}{c} Wx \succeq r \ x \in \mathbb{R}^p, ext{amount of products, 100g} & x \succ 0 \end{array}$$

$$x \in \mathbb{R}^p, ext{amount of products, 100g}$$

$$f \to \min_{x,y,z}$$
 Examples of Linear Programms

**Example: Diet problem** Proteins Carbs Amount per 100g Fats  $W \in \mathbb{R}^{n imes p}$ Calories Vitamin D  $\min c^T x$ 

 $c\in\mathbb{R}^p,$  price per 100g  $x\in\mathbb{R}^p$   $r\in\mathbb{R}^n,$  nutrient requirements  $x\in\mathbb{R}^p$  , amount of products, 100g  $x\succ 0$ 

Imagine, that you have to construct a diet plan from some set of products: bananas, cakes, chicken, eggs, fish. Each of the products has its vector of nutrients. Thus, all the food information could be processed through the matrix W. Let us also assume, that we have the vector of requirements for each of nutrients  $r \in \mathbb{R}^n$ . We need to find the cheapest configuration of the diet, which meets all the requirements:

$$egin{aligned} \min_{x \in \mathbb{R}^p} c^ op x \ & ext{s.t.} \ Wx \succeq r \ & x_i \geq 0, \ i = 1, \dots, n \end{aligned}$$

Examples of Linear Programms

#### Minimization of convex function as LP

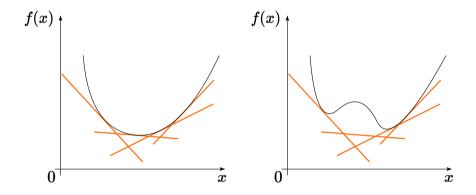

Figure 1: How LP can help with general convex problem

• The function is convex iff it can be represented as a pointwise maximum of linear functions.

#### Minimization of convex function as LP

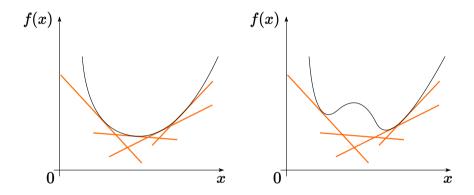

Figure 1: How LP can help with general convex problem

- The function is convex iff it can be represented as a pointwise maximum of linear functions.
- In high dimensions, the approximation may require too many functions.

#### Minimization of convex function as LP

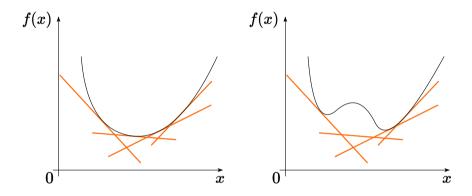

Figure 1: How LP can help with general convex problem

- The function is convex iff it can be represented as a pointwise maximum of linear functions.
- In high dimensions, the approximation may require too many functions.
- More efficient convex optimizers (not reducing to LP) exist.

The prototypical transportation problem deals with the distribution of a commodity from a set of sources to a set of destinations. The object is to minimize total transportation costs while satisfying constraints on the supplies available at each of the sources, and satisfying demand requirements at each of the destinations.

How to derive LP?

Max-min

$$\begin{aligned} & \min_{x \in \mathbb{R}^n} c^\top x & \max_{x \in \mathbb{R}^n} -c^\top x \\ \text{s.t. } & Ax \leq b & \text{s.t. } & Ax \leq b \end{aligned}$$

Max-min

$$\begin{aligned} & \min_{x \in \mathbb{R}^n} c^\top x & \max_{x \in \mathbb{R}^n} -c^\top x \\ \text{s.t. } & Ax \leq b & \text{s.t. } & Ax \leq b \end{aligned}$$

Equality to inequality

$$Ax = b \leftrightarrow \begin{cases} Ax \le b \\ Ax \ge b \end{cases}$$

Max-min

$$\begin{aligned} & \min_{x \in \mathbb{R}^n} c^\top x & \max_{x \in \mathbb{R}^n} -c^\top x \\ \text{s.t. } & Ax \leq b & \text{s.t. } & Ax \leq b \end{aligned}$$

Equality to inequality

$$Ax = b \leftrightarrow \begin{cases} Ax \le b \\ Ax \ge b \end{cases}$$

• Inequality to equality by increasing the dimension of the problem by m.

$$Ax \le b \leftrightarrow \begin{cases} Ax + z = b \\ z \ge 0 \end{cases}$$

Max-min

$$\begin{aligned} & \min_{x \in \mathbb{R}^n} c^\top x & \max_{x \in \mathbb{R}^n} -c^\top x \\ \text{s.t. } & Ax \leq b & \text{s.t. } & Ax \leq b \end{aligned}$$

Equality to inequality

$$Ax = b \leftrightarrow \begin{cases} Ax \le b \\ Ax \ge b \end{cases}$$

• Inequality to equality by increasing the dimension of the problem by m.

$$Ax \le b \leftrightarrow \begin{cases} Ax + z = b \\ z \ge 0 \end{cases}$$

Unsigned variables to nonnegative variables.

$$x \leftrightarrow \begin{cases} x = x_{+} - x_{-} \\ x_{+} \ge 0 \\ x_{-} \ge 0 \end{cases}$$

# **Example: Chebyshev approximation problem**

$$\min_{x \in \mathbb{R}^n} \|Ax - b\|_{\infty} \leftrightarrow \min_{x \in \mathbb{R}^n} \max_{i} |a_i^T x - b_i|$$

Could be equivalently written as an LP with the replacement of the maximum coordinate of a vector:

### **Example: Chebyshev approximation problem**

$$\min_{x \in \mathbb{R}^n} ||Ax - b||_{\infty} \leftrightarrow \min_{x \in \mathbb{R}^n} \max_{i} |a_i^T x - b_i|$$

Could be equivalently written as an LP with the replacement of the maximum coordinate of a vector:

$$\begin{aligned} \min_{t \in \mathbb{R}, x \in \mathbb{R}^n} t \\ \text{s.t. } a_i^T x - b_i \leq t, \ i = 1, \dots, n \\ - a_i^T x + b_i \leq t, \ i = 1, \dots, n \end{aligned}$$

### $\ell_1$ approximation problem

$$\min_{x \in \mathbb{R}^n} \|Ax - b\|_1 \leftrightarrow \min_{x \in \mathbb{R}^n} \sum_{i=1}^n |a_i^T x - b_i|$$

Could be equivalently written as an LP with the replacement of the sum of coordinates of a vector:

 $f \to \min_{x,y,z}$  How to derive LP?

# $\ell_1$ approximation problem

$$\min_{x \in \mathbb{R}^n} \|Ax - b\|_1 \leftrightarrow \min_{x \in \mathbb{R}^n} \sum_{i=1}^n |a_i^T x - b_i|$$

Could be equivalently written as an LP with the replacement of the sum of coordinates of a vector:

$$\min_{t \in \mathbb{R}^n, x \in \mathbb{R}^n} \mathbf{1}^T t$$
 s.t.  $a_i^T x - b_i \leq t_i, \ i = 1, \dots, n$  
$$-a_i^T x + b_i \leq t_i, \ i = 1, \dots, n$$

$$\mu_j = rac{b_j - a_j^T x_{\mathcal{B}}}{a_j^T d}$$

• Define the new vertex, that you will add to the new basis:

$$t = \arg\min_{j} \{\mu_{j} \mid \mu_{j} > 0\}$$
  $\mathcal{B}' = \mathcal{B} \setminus \{k\} \cup \{t\}$   $x_{\mathcal{B}'} = x_{\mathcal{B}} + \mu_{t}d = A_{\mathbf{p}'}^{-1}b_{\mathcal{B}'}$ 

Note, that changing basis implies objective function decreasing

$$f \to \min_{x,y,z}$$
 Simplex Algorithm

 $c^{T}x_{B'} = c^{T}(x_{B} + \mu_{t}d) = c^{T}x_{B} + \mu_{t}c^{T}d$ 

We aim to solve the following problem:

$$\min_{x \in \mathbb{R}^n} c^\top x$$
 s.t.  $Ax < b$ 

The proposed algorithm requires an initial basic feasible solution and corresponding basis.

We aim to solve the following problem:

We start by reformulating the problem:

y > 0, z > 0

$$\min_{x \in \mathbb{R}^n} c^\top x \\ \text{s.t. } Ax \leq b \\ \min_{y \in \mathbb{R}^n, z \in \mathbb{R}^n} c^\top (y-z) \\ \text{s.t. } Ay - Az \leq b$$

The proposed algorithm requires an initial basic feasible solution and corresponding basis.

(2)

We aim to solve the following problem:

We start by reformulating the problem:

y > 0, z > 0

$$\min_{x \in \mathbb{R}^n} c^\top x$$

$$\sup_{y \in \mathbb{R}^n, z \in \mathbb{R}^n} c^\top (y - z)$$
s.t.  $Ax \le b$ 
s.t.  $Ay - Az \le b$ 
(2)

The proposed algorithm requires an initial basic feasible solution and corresponding basis.

Given the solution of Problem 2 the solution of Problem 1 can be recovered and vice versa

$$x = y - z$$
  $\Leftrightarrow$   $y_i = \max(x_i, 0), \quad z_i = \max(-x_i, 0)$ 

Now we will try to formulate new LP problem, which solution will be basic feasible point for Problem 2. Which means, that we firstly run Simplex algorithm for Phase-1 problem and run Phase-2 problem with known starting point. Note, that basic feasible solution for Phase-1 should be somehow easily established.

$$\begin{aligned} & \min_{y \in \mathbb{R}^n, z \in \mathbb{R}^n} c^\top (y-z) \\ \text{s.t. } & Ay - Az \leq b \\ & y \geq 0, z \geq 0 \end{aligned} \qquad \text{(Phase-2 (Main LP))}$$

$$\begin{aligned} &\min_{y\in\mathbb{R}^n,z\in\mathbb{R}^n} c^\top(y-z)\\ \text{s.t. } &Ay-Az\leq b\\ &y\geq 0,z\geq 0 \end{aligned} \qquad \text{(Phase-2 (Main LP))}$$

$$\min_{\xi\in\mathbb{R}^m,y\in\mathbb{R}^n,z\in\mathbb{R}^n}\sum_{i=1}^m\xi_i$$
 s.t.  $Ay-Az\leq b+\xi$  
$$y>0,z>0,\xi>0$$

$$\min_{y \in \mathbb{R}^n, z \in \mathbb{R}^n} c^\top (y-z)$$
 s.t.  $Ay - Az \le b$  (Phase-2 (Main LP)) 
$$y > 0, z > 0$$

$$\min_{\xi \in \mathbb{R}^m, y \in \mathbb{R}^n, z \in \mathbb{R}^n} \sum_{i=1}^m \xi_i$$
 s.t.  $Ay - Az \leq b + \xi$  
$$y \geq 0, z \geq 0, \xi \geq 0$$
 (Phase-1)

If Phase-2 (Main LP) problem has a feasible solution, then Phase-1 optimum is zero (i.e. all slacks  $\xi_i$  are zero).

**Proof:** trivial check.

Simplex Algorithm

$$\min_{y \in \mathbb{R}^n, z \in \mathbb{R}^n} c^\top (y-z)$$
 s.t.  $Ay - Az \le b$  (Phase-2 (Main LP)) 
$$y > 0, z > 0$$

$$\min_{\xi \in \mathbb{R}^m, y \in \mathbb{R}^n, z \in \mathbb{R}^n} \sum_{i=1}^{\infty} \xi_i$$
 s.t.  $Ay - Az < b + \xi$ 

 $y > 0, z > 0, \xi > 0$ 

• If Phase-2 (Main LP) problem has a feasible solution, then Phase-1 optimum is zero (i.e. all slacks  $\xi_i$  are zero).

**Proof:** trivial check.

• If Phase-1 optimum is zero (i.e. all slacks  $\xi_i$  are zero), then we get a feasible basis for Phase-2. **Proof:** trivial check.

(Phase-1)

$$\min_{y \in \mathbb{R}^n, z \in \mathbb{R}^n} c^\top (y-z)$$
 s.t.  $Ay - Az \le b$  (Phase-2 (Main LP)) 
$$y > 0, z > 0$$

$$\min_{\xi \in \mathbb{R}^m, y \in \mathbb{R}^n, z \in \mathbb{R}^n} \sum_{i=1}^{\infty} \xi_i$$
 s.t.  $Ay - Az < b + \xi$ 

 $y > 0, z > 0, \xi > 0$ 

• If Phase-2 (Main LP) problem has a feasible solution, then Phase-1 optimum is zero (i.e. all slacks  $\xi_i$  are zero).

**Proof:** trivial check.

• If Phase-1 optimum is zero (i.e. all slacks  $\xi_i$  are zero), then we get a feasible basis for Phase-2. **Proof:** trivial check.

(Phase-1)

$$\min_{y\in\mathbb{R}^n,z\in\mathbb{R}^n}c^\top(y-z)$$
 s.t.  $Ay-Az\leq b$  (Phase-2 (Main LP)) 
$$y\geq 0, z\geq 0$$

$$\min_{\xi \in \mathbb{R}^m, y \in \mathbb{R}^n, z \in \mathbb{R}^n} \sum_{i=1}^m \xi_i$$
 s.t.  $Ay - Az \le b + \xi$  
$$y \ge 0, z \ge 0, \xi \ge 0$$

- If Phase-2 (Main LP) problem has a feasible solution, then Phase-1 optimum is zero (i.e. all slacks  $\xi_i$  are zero).
- **Proof:** trivial check.

   If Phase-1 optimum is zero (i.e. all slacks  $\xi_i$  are zero), then we get a feasible basis for Phase-2. **Proof:** trivial check.

• Now we know, that if we can solve a Phase-1 problem then we will either find a starting point for the simplex method in the original method (if slacks are zero) or verify that the original problem was infeasible (if slacks are non-zero).

(Phase-1)

$$\min_{y \in \mathbb{R}^n, z \in \mathbb{R}^n} c^\top (y-z)$$
 s.t.  $Ay - Az \le b$  (Phase-2 (Main LP)) 
$$y \ge 0, z \ge 0$$

$$\min_{\xi \in \mathbb{R}^m, y \in \mathbb{R}^n, z \in \mathbb{R}^n} \sum_{i=1}^m \xi_i$$
 s.t.  $Ay - Az \le b + \xi$  
$$y \ge 0, z \ge 0, \xi \ge 0$$

- If Phase-2 (Main LP) problem has a feasible solution, then Phase-1 optimum is zero (i.e. all slacks  $\xi_i$  are zero). **Proof:** trivial check.
- If Phase-1 optimum is zero (i.e. all slacks  $\xi_i$  are zero), then we get a feasible basis for Phase-2. **Proof:** trivial check.

Now we know, that if we can solve a Phase-1 problem then we will either find a starting point for the simplex method in the original method (if slacks are zero) or verify that the original problem was infeasible (if slacks are non-zero).
 But how to solve Phase 12 It has basis feasible solution (the problem has 2m to variables and the point below.

(Phase-1)

• But how to solve Phase-1? It has basic feasible solution (the problem has 2n + m variables and the point below ensures 2n + m inequalities are satisfied as equalities (active).)

$$z = 0$$
  $y = 0$   $\xi_i = \max(0, -b_i)$ 

⊕ ი

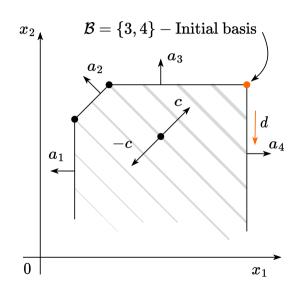

Convergence of the Simplex Algorithm

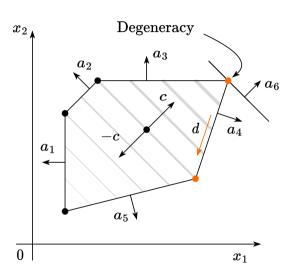

# Unbounded budget set

In this case, all  $\mu_j$  will be negative.

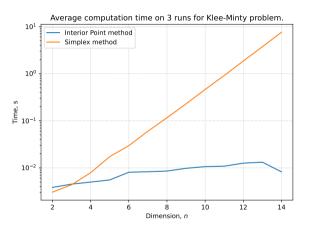

## **Degeneracy**

One needs to handle degenerate corners carefully. If no degeneracy exists, one can guarantee a monotonic decrease of the objective function on each iteration.

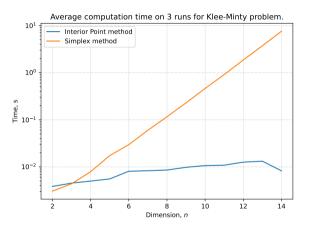

### **Exponential convergence**

 A wide variety of applications could be formulated as linear programming.

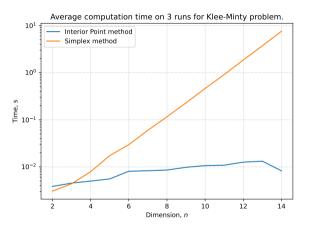

## **Exponential convergence**

- A wide variety of applications could be formulated as linear programming.
- Simplex algorithm is simple but could work exponentially long.

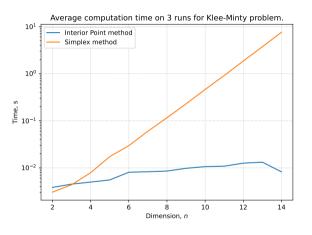

### **Exponential convergence**

- A wide variety of applications could be formulated as linear programming.
- Simplex algorithm is simple but could work exponentially long.
- Khachiyan's ellipsoid method (1979) is the first to be proven to run at polynomial complexity for LPs.
   However, it is usually slower than simplex in real problems.

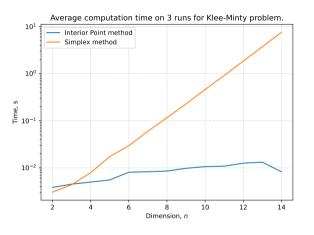

#### **Exponential convergence**

   However, it is usually slower than simplex in real problems.
- Major breakthrough Narendra Karmarkar's method for solving LP (1984) using interior point method.
- Interior point methods are the last word in this area.
   However, good implementations of simplex-based methods and interior point methods are similar for routine applications of linear programming.

### Klee Minty example

Since the number of edge points is finite, the algorithm should converge (except for some degenerate cases, which are not covered here). However, the convergence could be exponentially slow, due to the high number of edges. There is the following iconic example when the simplex algorithm should perform exactly all vertexes.

In the following problem, the simplex algorithm needs to check  $2^n-1$  vertexes with  $x_0=0$ .

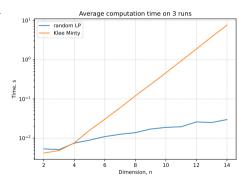

$$\max_{x \in \mathbb{R}^n} 2^{n-1} x_1 + 2^{n-2} x_2 + \dots + 2x_{n-1} + x_n$$
 s.t.  $x_1 \le 5$   

$$4x_1 + x_2 \le 25$$
  

$$8x_1 + 4x_2 + x_3 \le 125$$
  

$$\dots$$
  

$$2^n x_1 + 2^{n-1} x_2 + 2^{n-2} x_3 + \dots + x_n \le 5^n$$
  
 $x > 0$ 

**Mixed Integer Programming** 

Mixed Integer Programming

Consider the following Mixed Integer Programming (MIP):

$$z = 8x_1 + 11x_2 + 6x_3 + 4x_4 \to \max_{x_1, x_2, x_3, x_4}$$
s.t.  $5x_1 + 7x_2 + 4x_3 + 3x_4 \le 14$ 

$$x_i \in \{0, 1\} \quad \forall i$$

# Hardware progress vs Software progress

What would you choose, assuming, that the question posed correctly (you can compile software for any hardware and the problem is the same for both options)? We will consider the time period from 1992 to 2023.

Solving MIP with an old software on the modern hardware

speedup on MILP.

Solving MIP with a modern software on the old hardware

$$pprox 1.664.510 imes ext{speedup}$$

R. Bixby conducted an intensive experiment with benchmarking all CPLEX software version starting from 1992 to 2007 and measured overall software progress (29000 times), later (in 2009) he was a cofounder of

Gurobi optimization software, which gives additional  $\approx 81$ 

2 R. Bixby report

Moore's law states, that computational power doubles every 18 monthes.

R. Bixby conducted an intensive experiment with benchmarking all CPLEX software version starting from 1992 to 2007 and measured overall software progress

(29000 times), later (in 2009) he was a cofounder of Gurobi optimization software, which gives additional  $\approx 81$ 

speedup on MILP. It turns out that if you need to solve a MILP, it is better to use an old computer and modern methods than vice versa, the newest computer and methods of the early 1990s!<sup>2</sup>
